Prescription Fertilization

Fertilizer is an important step in plant health and quality. There are 16 essential nutrients for plant growth. In a natural setting these nutrients are readily available to the plant; however, in an urban setting or landscape it may be necessary for these nutrients to be manually applied. Because over fertilizing has such a harsh impact on the environment, Arborscapes is committed to prescription fertilizing.

The Arborscapes Difference

What Prescription Fertilizing means is before fertilizing, a laboratory soil or tissue sample will be taken to determine the amount of nutrients needed. Plants may show signs of being nutrient deficient but an incorrect soil pH could be preventing nutrient uptake. This is something that would only be detected through a soil sample. By utilizing available scientific practices, Arborscapes can not only fertilize, but fertilize specifically to the needs of your property.
