Soil Testing

Soil Testing is the process of taking a soil sample from your property and having it analyzed in a laboratory setting to better understand not only the issues your property may be having, but how to effectively treat them. Thanks to soil testing, we can more accurately determine the best ways to fertilize your trees and shrubs, as well as prevent diseases and infestations.

Prescription Fertilization and Soil Testing go hand in hand. Fertilizing is an essential step in plant health and quality. Urban landscapes may make it necessary for nutrients that would normally be readily available in non-urban settings to be applied manually. Because over-fertilization has a harsh impact on the environment, soil testing allows us to test your soil so that we may determine specifically which nutrients are needed. This allows us to not only fertilize, but to fertilize specifically to the needs of your property.
